# FREQUENCY OF SIMPSON'S PARADOX IN NAEP DATA 

James Terwilliger, NAEP Coordinator, Minnesota Department of Education<br>Milo Schield, Augsburg College, Director of the W. M. Keck Statistical Literacy Project

#### Abstract

Simpson's Paradox occurs for two states when their difference in scores has the opposite sign of the score differences for each of the state subgroups. Simpson's Paradox is a specific manifestation of statistical confounding. The paradox has been understood for many years but is usually regarded as simply a curious anomaly. The purpose of this paper is to show that Simpson's Paradox is not rare in NAEP data. NAEP public-school data are analyzed for 2000n Grade 4 Math and 2002 Grade 8 Reading. Conditions for a Simpson's reversal are presented. Approximately 100 instances of Simpson's Paradox are found per data set based on the influence of three confounders: family income, school location and race/ethnicity. In analyzing the influence of race/ethnicity two approaches are used. A straight forward approach generated 64 Simpson's reversals in the NAEP 2002 Grade 8 reading data of which 18 involve initial differences that are statistically significant. A more liberal approach generated 117 Simpson's reversals in the same data set of which 52 involve initial differences that are statistically significant. Either way these results support the claim that Simpson's Paradox is not rare in NAEP data. As a percentage of all pairs of state differences in the same data that are statistically significant, $4 \%$ are reversed using a conservative approach while $10 \%$ are reversed using a more liberal approach. All Simpson's reversals whether statistically significant or not - are argued to have 'journalistic significance' because of their political significance. Recommendations include ordering the data by key confounders as an adjunct when reporting results. The failure to allow adjustments for confounders can lead to a serious misinterpretation of the results which in turn can lead to questionable policies.

Keywords: Confounding, Standardization

## 1. THE NATIONAL ASSESSMENT OF EDUCATIONAL PROGRESS (NAEP)

NAEP is a unique large-scale assessment program. For over 30 years NAEP has collected data on national samples of $4^{\text {th }}, 8^{\text {th }}$ and $12^{\text {th }}$ graders. In 1990 NAEP began a biennial state-level assessment program which yields average scores for individual states in mathematics and reading at the $4^{\text {th }}$ and $8^{\text {th }}$ grade levels. NAEP offers the most reliable and widely acknowledged measure of student achievement across states. It is often referred to as the 'Gold Standard' in assessment. This study reports on the analysis of NAEP public school data from two data sets:

1. NAEP 2000n Grade 4 Math: The ' $n$ ' in '2000n' refers to data from students that were not allowed any special accommodations. ${ }^{1}$ Data are available for 41 jurisdictions. ${ }^{2}$
2. NAEP 2002 Grade 8 Reading: Use of accommodations as needed. Data available for 42 jurisdictions. ${ }^{2}$

To ensure the robustness of the results, data sets were chosen that involved different years (2002 vs. 2000), different tests (reading vs. math) and different grades (Grade 8 vs. Grade 4 ).

## 2. NAEP SCORES VERSUS PREVALENCE OF CONFOUNDERS

The NAEP 2000n Grade 4 math test is the basis for all the data in this section. Consider the influence of family income (school lunch payment status), school location (center city, urban-fringe and rural) and race/ethnicity (white, black, Hispanic and Asian) on the association between states and their NAEP state scores. ${ }^{3}$ The following plots show these associations.

[^0]Figure 1 plots state scores by the percentage of students who are not eligible for free or reduced-cost school lunch. Being non-eligible is based on a higher family income and it means having to pay full cost for school lunch. So, 'non-eligible', 'pay' and 'high income' are used interchangeably as are 'eligible,' 'non-pay' and 'low income.' The straight line models the relation between the state scores and the percentage of students who are non-eligible. The circles identify pairs of states that are examples of Simpson's reversals. These examples will be analyzed in detail in the next section.

Figure 1: State Scores vs. Percentage who are Non-Eligible for Free Lunch
Figure 2 plots state scores by the percentage of students who attend a central city school (as opposed to a rural or an urban-fringe school). As before, the circles identify examples of Simpson's reversals.

Figure 2: State Scores vs. Percentage who attend a Central City School

Figure 3 plots state scores by the percentage of students who are white (as opposed to non-white). Blacks, Hispanics and Asians are considered as non-whites in this case. Note that Simpson's reversals are not limited to those states circled. Those circled are just examples that will be analyzed in detail.

Figure 3: State Scores vs. Percentage of Students who are White
An obvious point in Figure 1 and Figure 3 is the strong association between state scores and the associated factor. The next step is to investigate specific examples of Simpson's reversals.

## 3. EXAMPLES OF REVERSALS AND CHANGES IN NAEP DATA

The NAEP 2000n Grade 4 math test is the basis for all the data in this section. Consider the influence of family income (school lunch payment status), school location (center city, urban-fringe and rural) and race/ethnicity (white, black, Hispanic and Asian) on the association between states and their NAEP state scores. The following tables present specific data for each of these confounders.

Table 1 shows state scores broken out by family income ${ }^{4}$. As shown in Table 1A, the state score is two points lower for Oklahoma (OK) than for Utah (UT). Yet when classified on family income (based on school lunch payment status), the state score for each subgroup score is higher for Oklahoma than for Utah. Note that the percentage of high income families is larger in Utah (64\%) than in Oklahoma (45\%) and students from high income families tend to score higher than those from low income families.

Table 1: State Scores Classified by Family Income

| State | All | High \$ | Low \$ |
| :---: | :---: | :---: | :---: |
| UT | 227 | 233 | 216 |
| OK | $\downarrow 225 \downarrow$ | $\uparrow 234 \uparrow$ | $\uparrow 218 \uparrow$ |

Table 1A UT vs. OK

| State | All | High \$ | Low \$ |
| :---: | :---: | :---: | :---: |
| MD | 222 | 233 | 207 |
| LA | $\downarrow 218 \downarrow$ | 233 | $\uparrow 211 \uparrow$ |

Table 1B: MD vs. LA

[^1]As shown in Table 1B, the state score is four points lower for Louisiana (LA) than for Maryland (MD). Yet when classified on family income, the state score for each subgroup is at least as high for Louisiana as for Maryland. Note that the percentage of high income families is greater in Maryland (58\%) than in Louisiana ( $32 \%$ ), and students from such families tend to score higher.
Table 2 shows state scores broken out by school location ${ }^{5}$. As shown in Table 2A, the state score is two points lower for New York (NY) than for Missouri (MO). Yet when classified by school location, the state score for each subgroup is at least as high for New York as for Missouri. Note that the percentage of students who attend non-city schools is higher in Missouri (78\%) than in New York (54\%) and that those attending such schools tend to do better.

Table 2 State Scores Classified by School Location

| State | All | City | Non-City |
| :---: | :---: | :---: | :---: |
| MO | 229 | 216 | 233 |
| NY | $\downarrow 227 \downarrow$ | 216 | $\uparrow 236 \uparrow$ |

Table 2A: MO vs. NY.

| State | All | City | Non-City |
| :---: | :---: | :---: | :---: |
| GA | 220 | 208 | 222 |
| TN | 220 | $\uparrow 213 \uparrow$ | $\uparrow 224 \uparrow$ |

Table 2B: GA vs. TN

As shown in Table 2B, the state score is the same for Tennessee (TN) as for Georgia (GA). Yet when classified by school location, the state score for each subgroup is two to five points higher for Tennessee than for Georgia. Note that the percentage of students who attend non-city schools is higher in Georgia ( $85 \%$ ) than in Tennessee ( $71 \%$ ) and that the students who attend non-city schools tend to do better.

Table 3 shows state scores broken out by race/ethnicity. As shown in Table 3A, the state score is two points lower for Texas (TX) than for Massachusetts (MA). But when classified by race/ethnicity, the state score for each subgroup is two to 16 points higher for Texas than for Massachusetts.

Table 3 State Scores Classified by Race/Ethnicity

| State | All | White | Black | Hisp. | Asian |
| :---: | :---: | :---: | :---: | :---: | :---: |
| MA | 235 | 241 | 210 | 208 | 237 |
| TX | $\downarrow 233 \downarrow$ | $\uparrow 243 \uparrow$ | $\uparrow 220 \uparrow$ | $\uparrow 224 \uparrow$ | $\uparrow 247 \uparrow$ |

## Table 3A: MA vs. TX

| State | All | White | Black |
| :--- | :---: | :---: | :---: |
| WV | 225 | 226 | 203 |
| LA | $\downarrow 218 \downarrow$ | $\uparrow 230 \uparrow+$ | $\uparrow 204 \uparrow$ |

How can it be that Texas students score higher than those in Massachusetts for every one of these four subgroups, yet those in Texas score lower overall? Some analysts find this puzzling and wonder if there is some error. Statisticians are well aware of this paradox. It can occur without any error in arithmetic.

The differences shown previously (zero to four points) may not seem that big. Consider a seven-point difference. As shown in Table 3B, the state score is seven points lower for Louisiana (LA) than for West Virginia (WV). Yet on each of the subgroups that were large enough ${ }^{6}$ to give statistically reliable scores, Louisiana scores higher than West Virginia.

This kind of reversal is Simpson's Paradox: the direction of an association in the overall group is the reverse of that in each of the subgroups. ${ }^{7}$ While statisticians know the conditions under which this reversal happens, this paradox is considered to be a fluke, an exception, an unlikely event. The purpose of this paper is to show that Simpson's Paradox is not rare in NAEP data.

The next step is to illustrate how Simpson's Paradox occurs.

[^2]
## 4. SIMPSON'S PARADOX

Simpson's Paradox involves confounding. Confounding occurs when two factors are mingled together. In a well-designed experiment with random assignment, the influence of confounding is minimized. In any observational study such as NAEP, confounding is always a concern - no matter how well designed the study. To understand how Simpson's Paradox can occur, consider the following figures.

Figure 4 illustrates the influence of family income in comparing Utah (UT) and Oklahoma (OK). The vertical axis is the NAEP score. The horizontal axis is the percentage of students who do not receive national school lunch subsidies (high income families). Students from high income families are on the right side; those from low income families are on the left. The scores are those shown in Table 1A. The scores for students from high income families ( 234 for OK, 233 for UT) are plotted on the right ( $100 \%$ high income families). The scores for students from low income families ( 218 for OK, 216 for UT) are plotted on the left ( $0 \%$ high income families).

The line connecting the two subgroup scores for a given state is a weighted average line. The state average NAEP score will lie on that line at a point determined by the percentage of families in the state who are high income: $64 \%$ in Utah and $45 \%$ in Oklahoma. The weighted average score for Utah is 227 : the intersection of the vertical $64 \%$ line with the UT weighted-average line. The weighted average score for OK is 225 : the intersection of the vertical $45 \%$ line with the OK weighted-average line. The state score is two points higher for Utah (227) than for Oklahoma (225).

Figure 4: Simpson's Paradox: UT vs. OK
To take into account the difference in family incomes, standardized scores are calculated. Standardized scores are scores that would have been obtained if each state had the same mix of family incomes as they have collectively. If $58 \%$ of these students live in OK then $53 \%$ of all these students in both states taken collectively had high family incomes. ${ }^{8}$ As shown in Figure 4, the standardized state score is two points

[^3]higher for Oklahoma (227) than for Utah (225). Adjusting for the influence of family income reversed the original association between state scores. Oklahoma has 'overtaken' Utah.

Figure 5 illustrates the influence of race/ethnicity in comparing Louisiana (LA) and West Virginia (WV). The generation of Figure 5 proceeds in the same manner as the generation of Figure 4. But now the horizontal axis is the percentage of students who are white. As separate groups, white students are on the right side; non-whites on the left. The scores shown in Table 3B are plotted and weighted average lines are generated. The weighted average score for West Virginia is 225 ( $95 \%$ are white) and for LA is 218 ( $53 \%$ are white). The state score is seven points higher for West Virginia (225) than for Louisiana (218).

Figure 5: Simpson's Paradox: LA vs. WV
As before, standardized state scores are calculated using the confounder mixture that is found when both states are combined. If $73 \%$ of these $4^{\text {th }}$ grade students are in LA, then $64 \%$ of the $4^{\text {th }}$ grade students in both states are white. ${ }^{9}$ The standardized state score is three points higher for Louisiana (221) than for West Virginia (218). Taking into account a relevant difference between two states (percentage of white) reversed the ranking between the states (LA and WV). West Virginia has been 'overtaken' by Louisiana.
For more on the nature and background of this type of graph, see Wainer (2002), Baker and Kramer (2001), Schield (2004) and Wainer (2004).

## 5. SUFFICIENT CONDITIONS FOR A REVERSAL OR CHANGE

Standardization is a process of generating new scores from the existing data that take into account the influence of a confounder. The graphical technique illustrated in Figure 4 and Figure 5 works well when the confounder has two values. See Schield (2004). But this technique does not work when the confounder has more than two values. Simpler sufficient conditions were used to identity a reversal or change that could handle multiple subgroups.

Reversal: a reversal of order in rank between two states after taking into account a confounder. State A has a lower score (higher rank number) than B , but after standardization A has a higher score

[^4](lower rank number) than B. Three conditions are jointly sufficient for a reversal. (1) The overall mean score for state $A$ is lower than that for state $B$. (2) The mean score for each subgroup in State A is at or above that for the corresponding subgroup in State B. (3) The mean score for at least one subgroup in State A is above that of the corresponding subgroup in State B. These conditions define a reversal commonly referred to as Simpson's Paradox. ${ }^{10}$

Change: a change in rank of two states after taking into account a confounder. A change occurs when the first condition above is replaced with this: (4) The overall mean score for State A is lower than or equal to that for state B. ${ }^{11}$ All reversals involve changes, but not all changes involve reversals.

Using these definitions the examples presented in Table 1 (A and B), Table 2A and Table 3 (A and B) involve Simpson's reversals. The example in Table 2B involves a non-reversing change.

## 6. RESULTS

The following tables summarize the number of Simpson's reversals and changes obtained when applying the aforementioned conditions to the NAEP data for various confounders. Technical details are shown in Appendix B and in the appendices listed in the following tables. 'Pairs' indicates the number of state pairs compared. ${ }^{12}$ 'Change' and 'Reverse' indicates the number of changes and Simpson's reversals.
'Statistically Significant' indicates an initial difference in a pair of state NAEP scores that is statistically significant at the $5 \%$ level as determined by the NAEP data tool. ${ }^{13}$ A reversal was considered statistically significant if the initial difference was statistically significant. Note that difference being tested is not the difference in standardized scores: scores generated by giving two units a standard mixture of a given confounder; the difference is that in the original scores.

|  |  | ALL |  |  | Statistically Significant |  | Source |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Confounder | States | Pairs | Change | Reverse | Pairs | Reversals | $\%$ | Appendix |
| School Lunch: Two groups | 39 | 741 | 23 | 15 | 504 | 0 | $0 \%$ | E |
| School Location: All ${ }^{14}$ | 38 | 703 | 4 | 1 |  | 0 | $0 \%$ |  |
| Race/ethnicity: All | 41 | 820 | 123 | 97 | 548 | 43 | $8 \%$ | F |
| Race: White vs. Non-white | 39 | 741 | 62 | 43 | 504 | 11 | $2 \%$ | G |

Table 4 Results for NAEP 2000n Grade 4 Math

|  |  | ALL |  |  | Statistically Significant |  |  | Source |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Confounder | States | Pairs | Change | Reverse | Pairs | Reverse | \% | Appendix |
| School Lunch: Two groups | 40 | 780 | 31 | 19 | 505 | 1 | $0.2 \%$ | H |
| School Location: All | 39 | 741 | 3 | 3 |  | 0 | $0 \%$ |  |
| Race/Ethnicity: All | 40 | 780 | 137 | 117 | 505 | 52 | $10 \%$ | I |
| Race: White vs. Non-white | 40 | 780 | 82 | 64 | 505 | 18 | $4 \%$ | J |

Table 5 Results for NAEP 2002 Grade 8 Reading

[^5]Note that comparisons involving race/ethnicity are approached in two ways. The white vs. non-white approach always involves comparable subgroups; the 'all' approach involves comparisons between states with some missing subgroups: subgroups that are not comparable. The latter approach has some assumptions that may be disputable whereas the former is straightforward. See Appendix A for details.

These two approaches to handling race/ethnicity give different results:

- Using a straightforward white/non-white approach, there are 64 Simpson's reversals in the NAEP 2002 data of which 18 involve initial differences that are statistically significant. In the NAEP 2000n data there are 46 Simpson's reversals of which 11 involve initial differences that are statistically significant.
- Using the more disputable 'all' approach involving non comparable subgroups, there are 117 Simpson's reversals in the NAEP 2002 data of which 52 involve initial differences that are statistically significant. In the NAEP 2000n data there are 97 Simpson's reversals of which 43 involve initial differences that are statistically significant.
Either way, these results support the claim that Simpson's reversals are not rare in NAEP data.
In the NAEP 2002 Grade 8 Reading data, 505 of the differences in state scores are statistically significant according to the NAEP Data Tool. Of these, 18 (4\%) are reversed using the white-nonwhite approach while $52(10 \%)$ are reversed using the more liberal 'all' approach. Up to $10 \%$ of the statistically significant differences in the 2002 state NAEP Grade 8 Reading scores are reversed by taking into account race. This high prevalence of Simpson's Paradox among statistically significant differences in state scores indicates that all comparisons of state scores must be treated with caution - even those involving differences that are statistically significant. Statistical significance does not eliminate confounding.

## 7. 'JOURNALISTIC SIGNIFICANCE'

NAEP is very careful in noting only those differences that have statistical significance. This care is shown in the online warning, "NOTE: Observed differences are not necessarily statistically significant." This care is also shown in only making comparisons (cross-sectional or longitudinal) that are statistically significant. But Education Departments and journalists may not be as careful. News stories involving NAEP data often compare state scores with previous scores and with those of others states regardless of their statistical significance. ${ }^{15}$ This may be done using point differences or rank differences. Since these comparisons are being reported they obviously have 'journalistic significance' - perhaps because federal controls and monies give these comparisons political significance. Given that these kinds of changes and reversals are newsworthy regardless of their statistical significance, all the changes obtained (at least 150 per data set) are said to have 'journalistic significance.'

## 8. PRESENTING CONFOUNDING

Simpson's Paradox reversals are an extreme form of confounding. There are many instances of confounding that do not involve Simpson's Paradox. One way of presenting confounding without adjusting the data is to use rank-based measures. We recognize there are problems in using ranks. NAEP does not currently publish ranks with their online data tool. Ranks can obscure big difference and magnify small ones. Talking about a change in rank as an increase is confusing since a higher rank has a lower number. Graphing ranks requires that changes in ranks may have journalistic significance without being statistically significant, much less statistically important. The following are three specific pitfalls associated with using ranks:
(1) Equal Scores Problem. When multiple states have the same NAEP score, they have the same rank. To illustrate this point, suppose that of the 48 states, 46 had the same score, with one state higher and one lower. Any of the 46 states in the middle could truthfully say, there is only one state that did better. Yet, it could truthfully be said that each of these 46 states finished $2^{\text {nd }}$ to last. A related problem

[^6]is what rank should be assigned when states have equal scores. Same-ranked states get the highest rank possible in Excel but get the average rank in SPSS. In the 46-states tied example, Excel gives one $1^{\text {st }}$ place, 46 in $2^{\text {nd }}$ place and one in $48^{\text {th }}$ place whereas SPSS gives one $1^{\text {st }}$ place, 46 in $24.5^{\text {th }}$ place and one in $48^{\text {th }}$ place. However, it is awkward to speak of a state being in $24.5^{\text {th }}$ place.

A simple solution to this equal-scores problem is to obtain greater precision. The results of using two digits after the decimal are shown in Appendix C and Appendix D. Although the increased precision certainly leads to 'hairsplitting', it does decrease other equally contentious problems.
(2) Different States Problem. Comparing the ranks of a state for two different sub groups is not meaningful if any state does not have data for both subgroups. This happens often with racial/ethnic subgroups as shown in Appendix D. The rankings of states for each racial/ethnic subgroup are not comparable because the number of jurisdictions for specific subgroups varies from 41 for white students to 13 for Asian students. Obviously it is misleading to say that Utah ranks higher among Asians (13th) than among whites (27th) since there are only 13 states with a statistically reliable prevalence of Asians. Utah is last among Asians.

A simple solution for this 'different numbers of states' problem is to use percentiles. Appendix C presents ranks and percentiles as generated from scores using Excel for white vs. non-white students. Percentiles for state scores by race are shown in Appendix D.
(3) Rank Explanation Problem. Explaining a state's overall rank in terms of the state's rank for each subgroup can be misleading. This is shown in Appendix C. Note that Iowa ranks $5^{\text {th }}$ overall, $14^{\text {th }}$ among white students and $5^{\text {th }}$ among non-whites. It is tempting to say that Iowa is 'pulled up' from the $14^{\text {th }}$ place rank of its white students to $5^{\text {th }}$ place overall by the $5^{\text {th }}$ place rank of the non-white students. Similarly Vermont ranks $9^{\text {th }}$ overall, $20^{\text {th }}$ among white students and $6^{\text {th }}$ among non-whites. It is tempting to say that Vermont is 'pulled up' from $20^{\text {th }}$ place among whites to $9^{\text {th }}$ place overall by the $6^{\text {th }}$ place rank of the non-white students.

While this 'pulled-up' style of explanation is totally appropriate for a weighted average, it is not appropriate for ranks or percentiles. Unlike weighted averages, the rank of the overall group is not algebraically determined by the ranks and proportions of the subgroups. It is difficult to explain New York's $21^{\text {st }}$ place overall rank as being due to its $8^{\text {th }}$ place rank among white and its $13^{\text {th }}$ place rank among non-whites. It is difficult to explain Minnesota's 1 st place rank overall as being due to its $7^{\text {th }}$ place rank among whites and its $3^{\text {rd }}$ place rank among non-whites. Since percentiles are just scaled ranks, the use of 'weighted-average' style explanations is inappropriate there also.

A solution for this 'rank-explanation problem' is to avoid such explanation for ranks or percentiles. .
In summary, while ranks and percentiles can be misleading and may reflect differences that are little more than 'splitting hairs', they can call attention to differences between subgroups and the overall group that would otherwise involve adjusting data for the influence of the confounder. So long as one doesn't try to explain the overall percentile by the percentiles of the subgroups, then comparing the overall percentile with a subgroup percentile can be very useful in demonstrating the influence of a confounder. Figure 6 shows 2000n NAEP Grade 4 Math percentiles by state overall and for just the white students. A higher percentile indicates a higher score.

Figure 6: State Percentiles: White-only versus Overall
States below the line have percentiles that are lower for their white students than for their overall mix of students (e.g., Indiana, Iowa, Vermont and Maine). States above the line have percentiles that are higher for their white students than for their overall mix of students (e.g., Texas, Virginia and New York). This kind of comparison of percentiles between overall and white-only can readily indicate the influence of the non-white students. Appendix C shows the state scores, ranks and percentiles for whites and non-whites. Appendix D shows state ranks and percentiles by racial/ethnic group.

## 9. NAGB POLICY ON ADJUSTING DATA

Adjusting data for confounders is controversial. In 1994, the National Assessment Governing Board (NAGB) reviewed this matter. The Board noted that "one of the methods being considered would provide for reporting across-state comparisons in an 'adjusted' or 'predicted' form based on ethnic and other demographic characteristics or on 'opportunity to learn' variables such as instructional approaches and time on task." The board then reaffirmed its 1989 policy which stated that "no levels of predicted or adjusted performance will be presented by NAEP for individual states." The Board notes that "any adjusted or predicted scores would be subject to serious methodological and political challenge and would be contrary to the strong national commitment to encouraging high standards for all children." NAGB (1994). But there are political implications in not adjusting. It may be counterproductive to hold schools and states accountable for things not under their control. One way to handle this is to present adjusted scores as an adjunct to the actual scores. This would allow methodological and political issues to be discussed after data have been adjusted using techniques that are methodologically sound.

## 10. RACE

This preliminary investigation indicates that Simpson's reversals are more common when adjusting for race/ethnicity than when adjusting for family income or school location. Adjusting state scores for differences in race/ethnicity seems more contentious than adjusting for family income or school location. But adjusting for race does not imply that there are genetic differences between racial/ethnic groups or that these score differences are caused by genetic differences. Racial/ethnic differences may be related to differences in a host of factors (socio-economic status, parental education, reading materials in the home, culture, etc.) some of which may not be readily measured. The importance of analyzing education outcomes by race is shown in the requirement of the 'No Child Left Behind' Act of 2001 that data be disaggregated. As Mukhopadhyay and Henze (2003) note: "Without data broken out according to racial, gender, and ethnic categories, schools would not be able to assess the positive impact intervention programs have on different groups of students." Once data are obtained and presented for various subgroups, the need to take such factors into account becomes more obvious.

## 11. RECOMMENDATIONS

The general recommendation is to emphasize that state means are influenced by a variety of potential confounders. These confounders can influence the overall scores and ranks of states. Four specific actions are recommended.
(1) NAEP should investigate ways to facilitate confounder-related analysis. For example, NAEP could also publish state scores as percentiles within various subgroups to facilitate comparisons. The score data by subgroups are already published by NAEP. It is just a matter of generating percentiles when appropriate. Presenting percentiles of states within subgroups avoids methodological issues involved in standardizing (Section 4) or adjusting (Section 9) and facilitates seeing the influence of confounding (Section 8).
(2) NAEP should generate adjusted scores for states after taking into account the influence of factors other than race/ethnicity that are outside the school's control such as school location and socio-economic factors. Doing so will allow a discussion of many methodological issues without taking on race.
(3) NAEP should generate adjusted scores for states after taking into account the influence of student race/ethnicity. This will allow for a discussion of those issues unique to race and ethnicity.
(4) NAEP should increase the sample sizes so that a 'journalistically significant' difference of one or two points would have statistical significance. Implementing this recommendation will be expensive but it allows smaller differences to be meaningfully distinguished and this may have political benefits.

## 12. CONCLUSIONS

This study finds that Simpson's Paradox is not a rare event in comparing state NAEP scores. When comparing the scores of some 40 states on three confounders, at least 150 changes were identified per dataset with at least 110 of these involving Simpson's Paradox reversals. In the NAEP 2002 Grade 8 Reading data, 55 Simpson's reversals involve initial differences that are statistically significant. These Simpson's reversals are $10 \%$ of all statistically-significant difference in state scores. Statistical significance does not eliminate Simpson's Paradox reversals. All Simpson's reversals - whether statistically significant or not - are newsworthy, which gives them 'journalistic significance.' It is recommended that state scores and ranks be compared for key subgroups, that adjusted scores be calculated for factors outside the schools control, and that these adjusted state scores be employed as an adjunct when reporting results.

Notes: This research was supported in part by a grant from the W. M. Keck Foundation to Augsburg College "to support the development of statistical literacy as an interdisciplinary discipline." This paper has not been reviewed or approved by the Minnesota State Department of Education, the U.S. Department of Education, the National Assessment of Educational Progress (NAEP) or any subunits thereof. This paper was presented at the annual meeting of the American Education Research Association (AERA) in San Diego on 16 April 2004.

Contacts: James Terwilliger is the NAEP Coordinator for Minnesota. His e-mail address is Jim.Terwilliger@state.mn.us. Milo. Schield is Director of the W. M. Keck Statistical Literacy project and Professor of Business Administration at Augsburg College. His e-mail address is Schield $@$,Augsburg.edu. This paper is at www.augsburg.edu/ppages/~schield and at www.StatLit.org.

[^7]
## Appendix A. MISSING DATA (LACK OF COMMON SUBGROUPS)

Missing data is a problem. In NAEP, the problem is that the amount of data obtained was too small to give statistically-reliable scores. Scores were not considered reliable if the associated subgroup had less than 60 subjects in the sample. Most of the instances involve race/ethnicity. This issue was addressed in two ways. The first involves grouping black, Hispanic and Asian into a non-white category so that all states had a non-white group that surpassed the NAEP minimum size requirement. ${ }^{17}$ The second involves imputing scores for the missing subgroups to allow comparisons of all state scores. The second gives bigger numbers than the first, but it is a more disputable approach.

If two jurisdictions do not have common subgroups, it seems there is little that can be said. But if the jurisdiction having the lower NAEP score has subgroup scores that are higher or at least as high for each of the common subgroups, this gives some evidence for concluding that the scores in the missing subgroups would be at least as high as those in the jurisdiction having the higher NAEP score. And as long as at least one of the scores in the lower state is greater than that in the common subgroup in the higher state, then we have satisfied the sufficient condition mentioned earlier. Now this argument from nearignorance is not very strong. A second argument is that the missing subgroups must be quite small as a percentage of students in that state. It is possible to have a reversal even if one of the subgroups in the lower state has a lower score than that of the common subgroup in the higher state. For these two reasons, the analysis of all four racial/ethnic groups assumes that if a reversal is justified by the common subgroups, it would not be contradicted by anything involving the missing groups. The extreme case involves Maine and Vermont ( $97 \%$ white) being compared against Mississippi (49\%), Texas (44\%), New Mexico ( $38 \%$ ) and California ( $38 \%$ ). Obviously this conclusion is very disputable. The reason for presenting this criterion is not to argue that it is true, but to argue that it a reasonable approach to handling the existing racial/ethnic differences between states.

## Appendix B. TECHNICAL DETAILS

This appendix indicates how the data and formula were entered into the spreadsheets shown in subsequent appendices. First, obtain the desired NAEP data by jurisdiction/state and by subgroup from the web. ${ }^{18}$ Copy the data to a spreadsheet and convert the state names to their two-character equivalents. ${ }^{19}$ The ordering of the states is critical. To locate all the reversals and changes in the lower-triangle (e.g., Appendix E), the sort order must be state average (descending) and the NAEP scores of all state subgroups must be ascending. ${ }^{20}$ Since Excel handles a maximum of three sort groups, in the case of race (Appendix F) this means sorting first on Black (A), Hispanic (A) and Asian (A), and then sorting on State Average (Descending) and White (Ascending). After the data has been appropriately ordered in a column format, it must be transposed into a row format as shown on the bottom of the table in Appendix E. ${ }^{21}$ Thus, states on the left are trying to overtake; states along the bottom are being overtaken.

[^8]The conditions for a change were entered as a spreadsheet formula into the upper-left hand cell. Consider a formula involving two subgroups where there is no missing data (e.g., Appendix E).
G8: $=\mathrm{IF}(\mathrm{AND}(\$ \mathrm{~B} 8<=\mathrm{G} \$ 48, \$ \mathrm{D} 8>=\mathrm{G} \$ 50, \$ \mathrm{E} 8>=\mathrm{G} \$ 51, \mathrm{OR}(\$ \mathrm{D} 8>\mathrm{G} \$ 50, \$ \mathrm{E} 8>\mathrm{G} \$ 51))=\mathrm{TRUE}, \mathrm{G} \$ 48-\$ B 8, " ")$
If the condition is true, then the difference in state scores (G48-B8) is shown; otherwise a blank ("") is shown. The condition for two subgroups with no missing data involves an AND of several conditions. First, the state score of the state on the left must be less than or equal to that of the state score below ( $\mathrm{B} 8<=\mathrm{G} 48$ ). Second, for each of the two subgroups the subgroup score in the state on the left must be greater than or equal to the score of that subgroup in the state on the bottom ( $\mathrm{D} 8>=\mathrm{G} 50, \mathrm{E} 8>=\mathrm{G} 51$ ). Third, at least one of the subgroup scores for the state on the left (those overtaking) must be greater than that of the state on the bottom (those overtaken): OR(D8>G50,E8>G51). The dollar signs are added to keep certain rows and columns fixed to facilitate copying the resulting formula to all cells in the table. If there are more sub-groups, additional items must be added. If there are missing values, then the formula becomes more complex. See the formula in the bottom line for Appendix F.

If the conditions for a change were satisfied, the cell showed the size difference between the two state scores. A value of zero indicates a non-reversing change. Any value greater than zero indicates a Simpson's Paradox reversal. ${ }^{22}$ The counts of states were obtained using the CountA function in combination with the CountBlank function. The maximum difference in state scores was obtained using the MAX function. Care should be taken in how one describes these changes. ${ }^{23}$

Statistical significance in the conditional formatting (the shaded areas) was estimated if the 95\% confidence intervals failed to overlap. The width of a $95 \%$ confidence interval was calculated based on the national mean of the standard errors for the states studied. ${ }^{24}$ Since the sample sizes were similar for all the states, the differences in standard errors largely reflected differences in the standard deviations. ${ }^{25}$

In the body of this paper, statistical significance was always determined using the exact approach using the NAEP data tool. This explains the difference between Appendix H ( 507 statistically significant differences of which 55 are reversed for an $11 \%$ rate) versus Table 5 ( 505 statistically significant differences of which 52 are reversed for a $10 \%$ rate). In the spreadsheets in the following appendices, those differences that were not statistically significant using the NAEP Data Tool but were statistically significant using the short-cut formula were italicized. Thus, in Appendix H, note the italicized value for OH-VT, NY-OH, and LA-TN. These three values are the difference between the 55 shown in the spreadsheet and the 52 shown in Table 5.

To obtain state scores with two-decimal accuracy, select ‘Customize Table' under 'User Options.' Change 'Degree of Precision' from 'zero digits' to 'two digits.' Obtaining scores with two-digits gives much higher accuracy for non-white means in states having a very small non-white population (e.g., Vermont and Maine). It also eliminates most ties in state rankings but that is incidental.
To obtain percentiles in Microsoft Excel, use $=100 *$ PercentRank(Array, Test, Significance) where Array is the complete list of scores, Test is the score of the state being tested and Significance is the digits of precision). If the values are non-matching, the PercentRank function returns $0 \%$ and $100 \%$ for two values, $0 \%, 50 \%$ and $100 \%$ for three values, $0 \%, 33 \%, 67 \%$ and $100 \%$ for four values, and $0 \%, 25 \%, 50 \%, 75 \%$ and $100 \%$ for five values. States having matching scores get assigned the highest rank but the lowest percentile possible in Excel.
The rounded values of these non-white scores were used for Vermont ( $97 \%$, 217), Maine $(97 \%, 224)$, West Virginia $(94 \%, 210)$, North Dakota $(91 \%, 212)$ and Iowa $(90 \%, 217)$ in Appendix G.

[^0]:    ${ }^{1}$ Accommodations are any non-standard conditions involved in the testing, e.g., allowing extra time. In 2000 NAEP was making a transition from traditional assessment in which no accommodations were permitted to the use of accommodations. That year the samples were randomly split with half the students being permitted to use accommodations that were deemed necessary while the other half was NOT allowed to use accommodations.
    ${ }^{2}$ Only jurisdictions from the contiguous 48 states were analyzed plus the Department of Defense schools: DESS and ODDS.
    ${ }^{3}$ In the interest of brevity, we refer to the mean NAEP score for a state simply as 'the state score.'

[^1]:    ${ }^{4}$ Federal guidelines identify a federal income-related criterion under which students in low-income families receive free or re-duced-fee school lunches. Based on student responses, students were classified into four groups: Not eligible, eligible, 'Don't know' and 'No answer.' NAEP generated scores for the first three groups and the state average. To reduce the subgroups to just two categories, students in the last three subgroups were combined. Given the score and prevalence of those in the 'High Income Family' sub group plus the state average, the score for those in the 'Low-Income Family' subgroup was calculated.

[^2]:    ${ }^{5}$ School locations are Central-City, Urban-Fringe and Rural. To reduce this to two categories, non-city scores were calculated based on the state score and the average score and prevalence of students at Central-City schools.
    ${ }^{6}$ NAEP does not report subgroup means for samples smaller than 60 ; these scores are not statistically 'reliable.'
    ${ }^{7}$ See Schield (1999) at www.StatLit.org/articles.

[^3]:    ${ }^{8}$ According to NAEP in 1999 there were 447,906 public-school K-8 students in OK ( 328,522 in UT). So, $58 \%$ of these students are in OK. If so for grade 4, the combined percentage who are white is $53 \%: 58 \%(0.45)+42 \%(0.64)$.

[^4]:    ${ }^{9}$ According to NAEP in 1999 there were 558,743 public-school K-8 students in LA (205,840 in WV). So $73 \%$ of these students are in LA. If so for grade 4 , the combined percentage who are white is $64 \%: 73 \%(0.53)+27 \%(0.95)$.

[^5]:    ${ }^{10}$ This definition is a slight broadening or generalization of the definition advanced in Schield and Burnham (2003) that required the score for each subgroup in State A to be above that for the corresponding subgroup in State B.
    ${ }^{11}$ The case where two states start with different scores (different ranks) and end up with the same score (same rank) is not analyzed. State A must have at least one subgroup that is below its match in B and at least one that is above.
    ${ }^{12}$ If there are N states, there are $\mathrm{N}(\mathrm{N}-1) / 2$ state pairs.
    ${ }^{13}$ To obtain data by state, complete first three steps in footnote 18. (4) Select the 'User Options' menu and select 'Check Significant Differences.' (5) In the popup window for the NAEP Data Tool Check Selection Criteria, select the 'Average Score Scale' option and press 'Continue.' The NAEP Data Tool then returns a table indicating whether the second state score is significantly higher ( $>$ ), lower $(<)$ or equal $(=)$ to the score of the first state. For more information about the differences, click on the 'Show Details' button at the bottom.
    ${ }^{14}$ Vermont was excluded since it does not have enough students in the Rural and Urban Fringe categories to give results that are statistically reliable so an exact match comparison is not possible.

[^6]:    ${ }^{15}$ A convenience survey of five press releases by state education departments found that all of them included comparisons involving differences or changes that were not statistically significant.

[^7]:    ${ }^{16}$ For a copy of this paper, see 'Teaching Stat Lit' at www.StatLit.org.

[^8]:    ${ }^{17}$ NAEP guidelines require that a subgroup have at least 60 students to be shown. If 3,000 students are tested in a state, then data for subgroups involving less than $2 \%(60 / 3000)$ of the students will not be shown.
    ${ }^{18}$ Go to http://nces.ed.gov/nationsreportcard/naepdata/search.asp. (1) Select a subject (Math), grade (4 ${ }^{\text {th }}$ ), jurisdiction (National/public) and category (Major Reporting Groups); press 'Continue.' (2) Check the year desired and select Major Reporting Group (1. All Students). This gives the national score. (3) From the User Options menu, select Add/Deletee Jurisdictions to obtain the score for each state. From the list of Jurisdictions, press Select All and then de-select those not desired (American Samoa, District of Colombia, Guam, Hawaii, Virgin Islands, etc.). Press the Accept Changes button. This gives NAEP scores by state. (4) From the User Options menu, select Add/Delete Subgroups. Select the subgroup desired (Race as Identified by School Records); Press Accept Changes.
    ${ }^{19}$ Recall that Arkansas is AR (not AK) and Arizona is AZ (not AR).
    ${ }^{20}$ A different sort order could change the location of results and of statistical significance (e.g., place some in the upper-right of the table), but a different sort order would not change the number of reversals or changes. The formula is copied throughout the entire table so two states are compared twice: once in lower left, once in upper right.
    ${ }^{21}$ To transpose data from columns to rows, copy the column data to the Clipboard and then place the cursor in the upper-left hand cell of the area being copied to. From the Edit menu, select the Paste-Special option. Check the Transpose box located near the bottom and press OK. (If formulas are involved, check the Values checkbox).

[^9]:    ${ }^{22}$ If space is a problem, the top row of state data can be eliminated (it is impossible for the top state to pass anyone higher) and the right column of state data can be eliminated (it is impossible for any state to pass the bottom state).
    ${ }^{23}$ It is important to distinguish changing the data from calculating a new score based on a combination of existing data and hypothetical weights. Statisticians (almost) never change the data. Avoid saying, "The data was changed to give both states the same mix of students," even though that may be readily understood. Instead one should say, "Scores were calculated or constructed using the same mix for both states." Speaking about changes in scores (raw vs. calculated) may be technically correct, but can lead the unwary to conclude the data have been changed.
    ${ }^{24}$ In the NAEP 2000n Grade 4 math, the standard errors ranged from a minimum of 0.7 to a maximum of 1.9 with a mean of 1.3. Multiplying this by 1.96 and doubling it to get the full width gave a range of 5.096 which rounded to five. In the NAEP 2002 Grade 8 reading, the standard errors ranged from a minimum of 0.5 to a maximum of 1.8 with a mean of 1.13 . Multiplying this by 1.96 and doubling it gave a range of 4.43 which rounded down to four. This approach has two weaknesses. (1) The range of standard errors is wide compared to the mean value. (2) This approach uses the same standard error for all states when in any given comparison of two states we need the unique standard error for just those two states. These weaknesses are somewhat mitigated since the goal is to indicate the general range where differences are statistically significant rather than to make precise measurements.
    ${ }^{25}$ For the NAEP 2000n Grade 4 math data, the associated width was about 5; for the NAEP 2002 Grade 8 reading data, the associated width was about 4. One reason for this decrease was that in 2000 the state samples were split between non-accommodations (2000n) and accommodations (2000) whereas in 2002 there was no split. Thus the relevant sample sizes in 2002 were about double those in 2000.
